Polymorphism

A closer look at types....

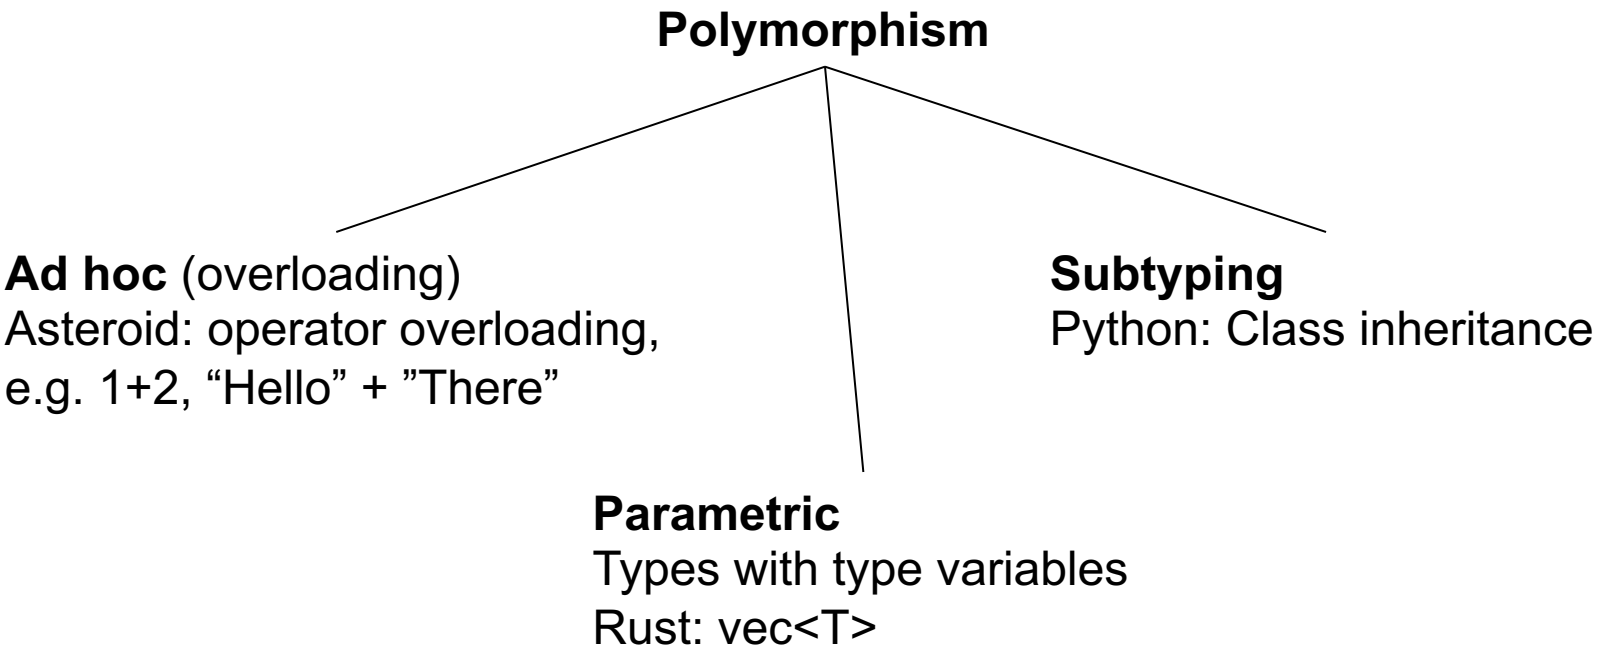
polymorphism ≡ comes from Greek meaning ‘many forms’

In programming:

Def: A function or operator is polymorphic if it has at least two possible types.

Polymorphism

Different type of polymorphisms



Polymorphism

- **Ad hoc polymorphism** or **overloading**: defines a function/operator name for an arbitrary set of individually specified types.
- **Parametric polymorphism**: when one or more types are not specified by name but by type variables that can represent any type.
- **Subtyping** or **subtype polymorphism**: when a name denotes instances of many different classes related by some common superclass.

https://en.wikipedia.org/wiki/Polymorphism_(computer_science)

Ad Hoc Polymorphism

Def: An overloaded function name or operator is one that has at least two definitions, all of different types.

Example: In Java the '+' operator is overloaded.

String s = "abc" + "def";

+: String * String → String

int i = 3 + 5;

+: int * int → int

Polymorphism

Example: Java allows user defined polymorphism with overloaded function names.

```
bool f (char a, char b) {
        return a == b;
}
```

f : char * char → bool

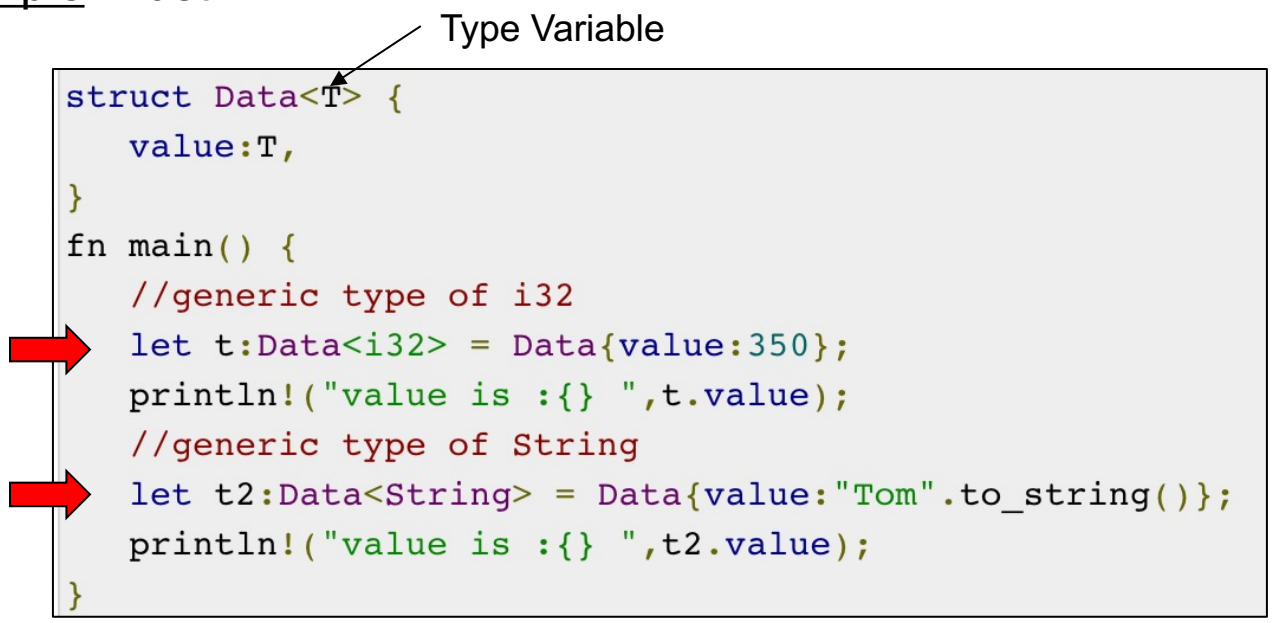
```
bool f (int a, int b) {
        return a == b;
}
```

f : int * int → bool

Parametric Polymorphism

Def: A function/structure exhibits parametric polymorphism if it has a type that contains one or more type variables.

Example: Rust



Source: https://www.tutorialspoint.com/rust/rust_generic_types.htm

Subtype Polymorphism

Def: A function or operator exhibits subtype polymorphism if one or more of its types have subtypes.

Subtype Polymorphism

Example: Java

```
class Cup { ... };
class CoffeeCup extends Cup { ... };
class TeaCup extends Cup { ... };

TeaCup t = new TeaCup();
Cup c = t;
```

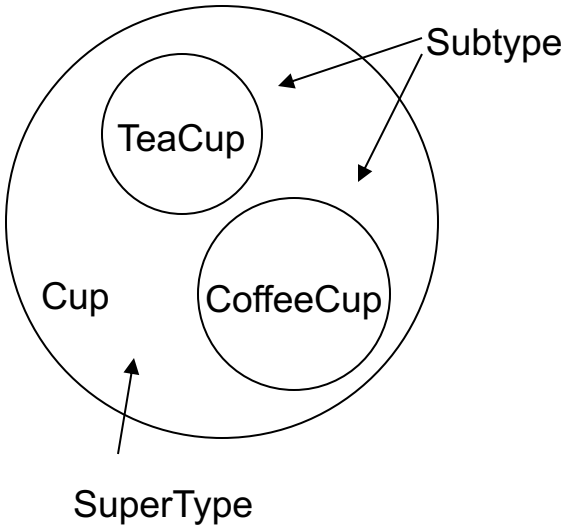
type coercion: TeaCup → Cup (safe!)

```
void fill (Cup c) {...}

TeaCup t = new TeaCup();
CoffeeCup k = new CoffeeCup();

fill(t);
fill(k);
```

subtype polymorphism



Duck Typing

- Duck typing in computer programming is an application of the duck test—"*If it walks like a duck and it quacks like a duck, then it must be a duck*"—to determine if an object can be used for a particular purpose. With normal typing, suitability is determined by an object's type. In duck typing, **an object's suitability is determined by the presence of certain methods and properties, rather than the type of the object itself.**

https://en.wikipedia.org/wiki/Duck_typing

Duck Typing

- Example: a polymorphic list with Duck Typing.
- Compare this to the subtype polymorphism example written in Rust…

```
class Duck:
    def fly(self):
        print("Duck flying")

class Sparrow:
    def fly(self):
        print("Sparrow flying")

class Whale:
    def swim(self):
        print("Whale swimming")

for animal in Duck(), Sparrow(), Whale():
    animal.fly()
```

Polymorphic list

Duck Typing

- Duck typing can also be more flexible in that only the methods actually called at runtime need to be implemented.
- Most dynamically typed languages implement Duck Typing.
